## **1. INTRODUCTION**

This document describes the functional electric tests performed on the camera of AMICA during the Environmental Test of Thermal vacuum cycling, carried out in Terni from 14th to 19th/03/2006 and is an integral part of following documents which explain the procedural aspects of the test:

- 1) Environmental Test Report: **Star Tracker Thermal Vacuum Cycling Test**, date: 06/07/06, rev: A01, prepared by : ing. Serena Borsini (file: ASTCFuncThCycling),
- 2) **Star\_Tracker\_TV\_test\_Plan\_\_050106**, APPENDIX\_1\_rev2,

The description which follows up is therefore to be seen as a separate section of a same report and all the references to the above mentioned documents maintain the same name.

The documentation of the test functionality is made up of two parts:

- 1) **Table of the current flow absorbed** during the 8 cycles of the test, to prove that the equipment has not suffered from catastrophically bad functioning during the test and that the absorption values are repetitive and characteristic in every environmental condition.
- 2) **Images of the CCD** which are those taken during the different phases of the test. For practical reasons the images shown are all those taken during the first cycle, mentioned in the Test Plan, and those taken during the last cycle, to prove that the functioning of the camera, although influenced by the environmental temperature, has always shown to be according to the aim of the project and that the camera reacts to the re-establishment of the environmental conditions returning to its initial response.

To evaluate the image quality of the camera it should be noticed that the CCD set up on board during this test is the same one that had previously been bombarded with heavy ions to a level by almost one order of magnitude higher than the level foreseen on board the ISS at SIRAD-INFN in Legnaro. The CCD consequently underwent an annealing process at 200°C to reduce as much as possible the thermic background noise caused by the bombardment.

The use of this CCD for the Thermal vacuum cycling test was decided to prove its capacity to support both the stress due to the bombardment and the stress due to extreme temperature cycles. As a consequence the images taken by the camera during the test show a level of background noise in the form of granularity of the image, especially at high temperature, which is by some orders of magnitude higher than that of the CCD which is going to be installed on AMICA. This noise is an exponential function of the temperature: with rising temperature it becomes the factor that sets a limit to the use of

the CCD, while with diminishing temperature it can be ignored compared to the electronic noise.

In some of the images shown there are some lighter spots which cluster together or line up. They are due to a sampling problem of the signal receiving section, outside of the vacuum chamber, that in the case of certain pixel values adds the constant value of 256 (out of 4095) to them: decoding error on 8<sup>th</sup> bit. This explains why the white spots are seen only in certain images.

## 2. THERMAL VACUUM CYCLING CURRENTS

PHASE	DAY	TIME	I(+12V) (mA)	I(-12V) (mA)	I(+3.3V) (mA)

### **3. CCD IMAGES**

Below the CCD images taken both during the complete first cycle and the last cycle are reported. The first one is the most representative for the camera behavior at the extreme temperture conditions, while the last one points out the camera surviving capability.

When requested by the test plan both a dark image and a bright image are shown. The bright image was taken with a lamp ligting the transparent window of the vacuum chamber. However, because the intensity of the diffused light into the chamber was not strictly controlled, the CCD sensitivity in the different working conditions can not be quantified.

An evaluation of the CCD image quality was carried out through the calculation of the average value and the variance of the CCD pixels intensity, inside a central 100x100 pixels area. Both values are reported at the side of the image as  $m$  and  $\sigma$ .

The names of the images follow those mentioned in the test plan.

Every image shown in the following text is obtained by adjusting contrast and luminosity at its best so as to make it suitable for printing.

***ELECTRONICS SETUP***

IMAGE: DARK\_23\_00\_14\_03.png, (  $m = 325.5$ ,  $\sigma = 1.03$  )
